Recall the lifespan of a star depends on its Mass

As Observed from the earth, the distance to all the stars within a cluster are ~ the same

Therefore the differences in brightness are directly related to the differences in Luminosity or energy output.

- distance effects are removed

HR Diagrams for Various Open Clusters

As Observed from the earth, the distance to all the stars within a cluster are ~ the same

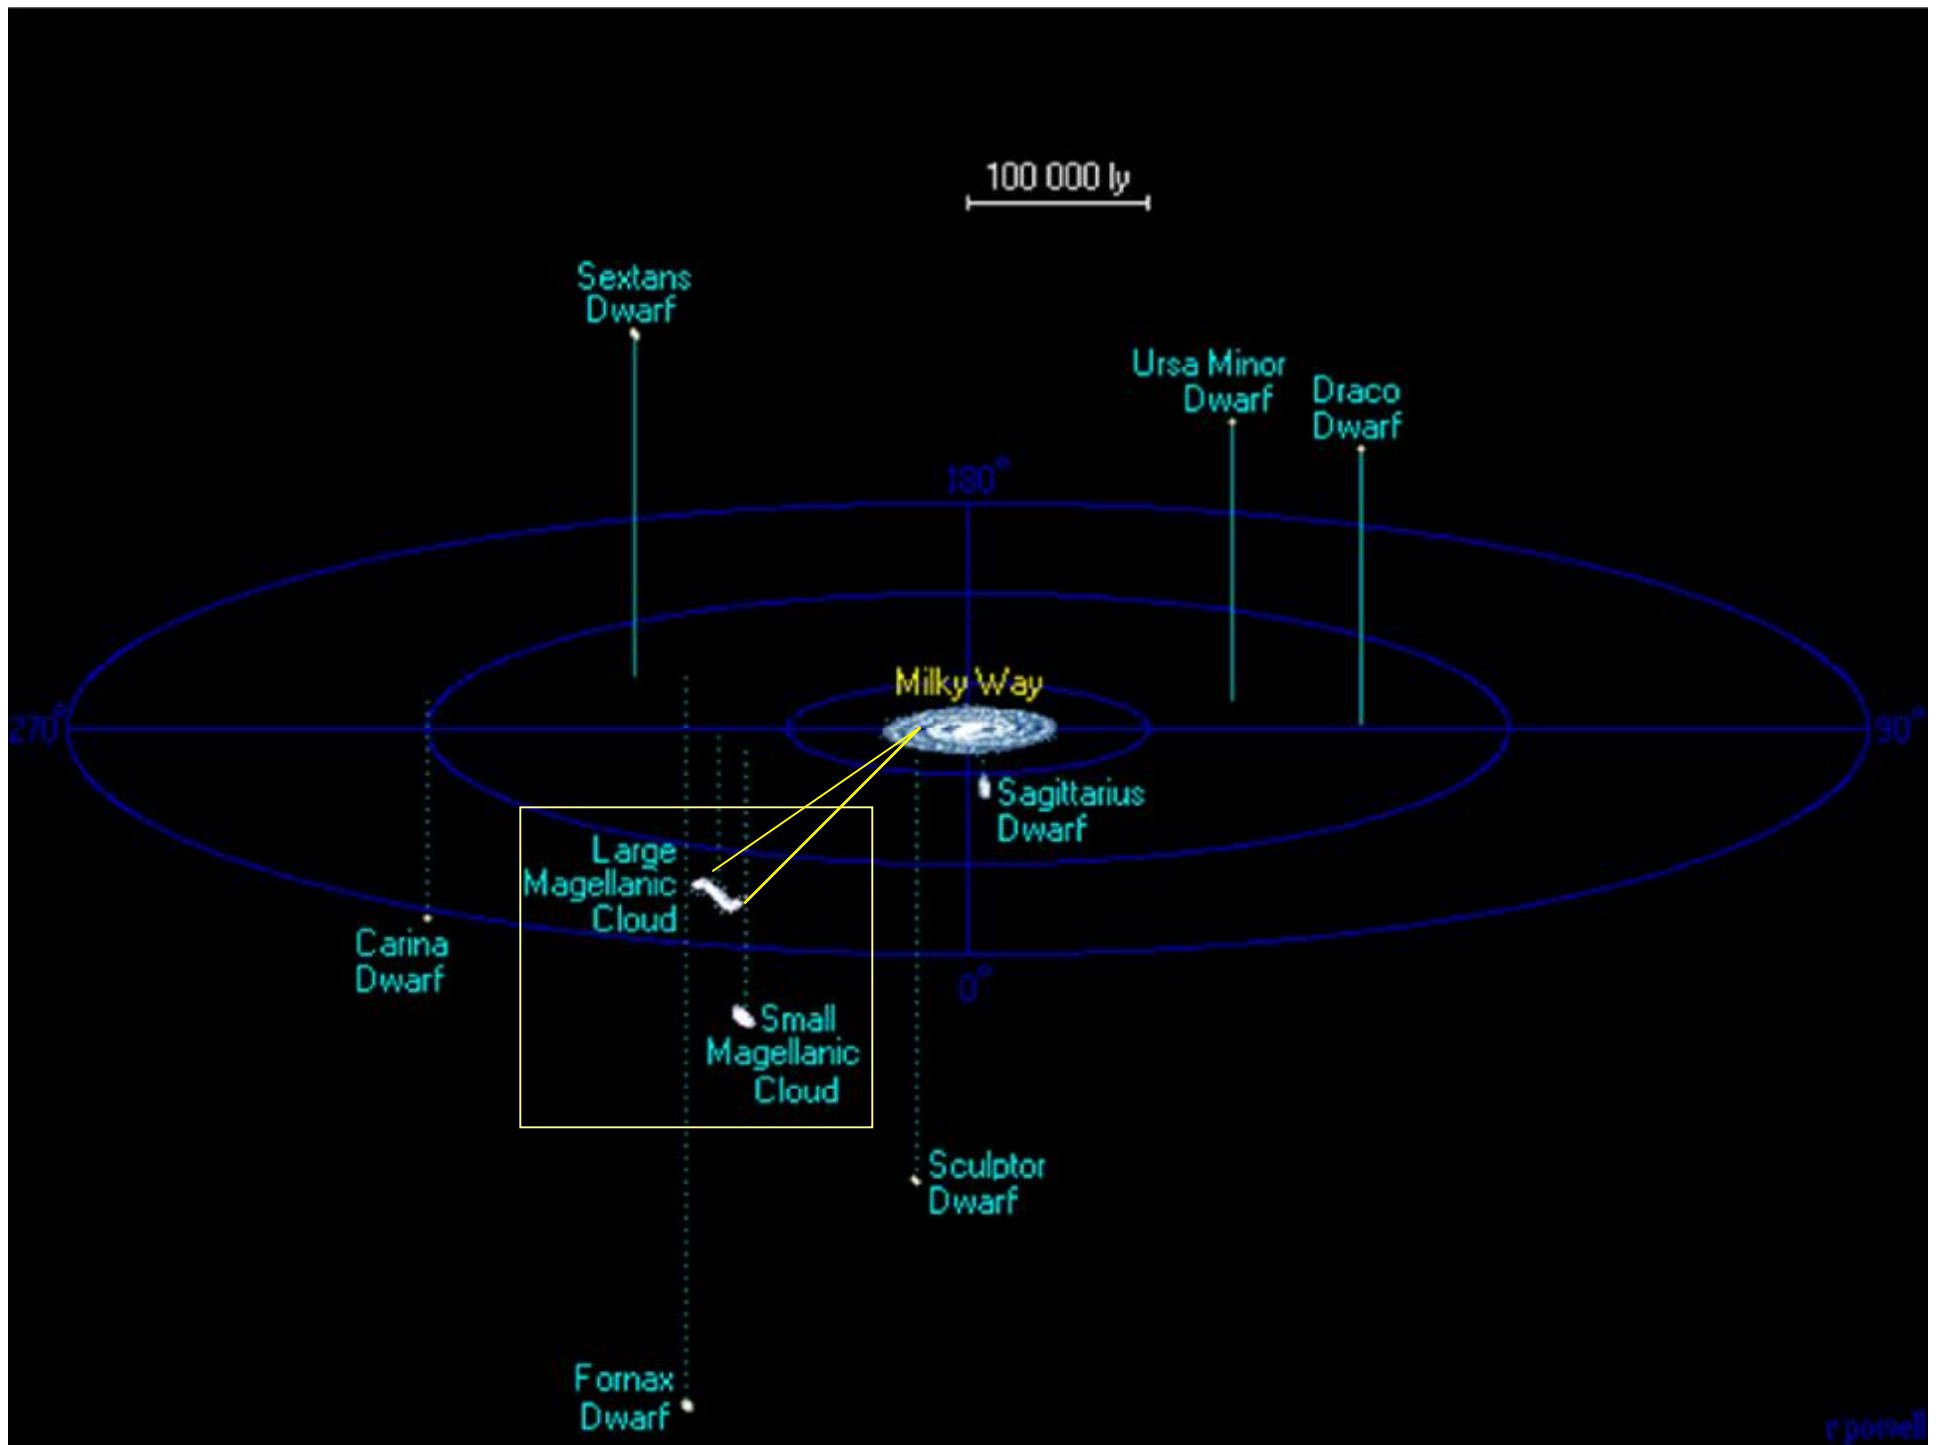

Therefore the differences in brightness are directly related to the differences in Luminosity or energy output.

- distance effects are removed

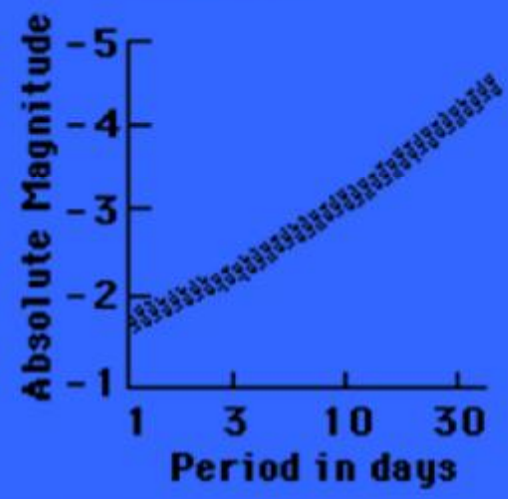

Open Cluster M7

The period-luminosity relation for Cepheid variables.

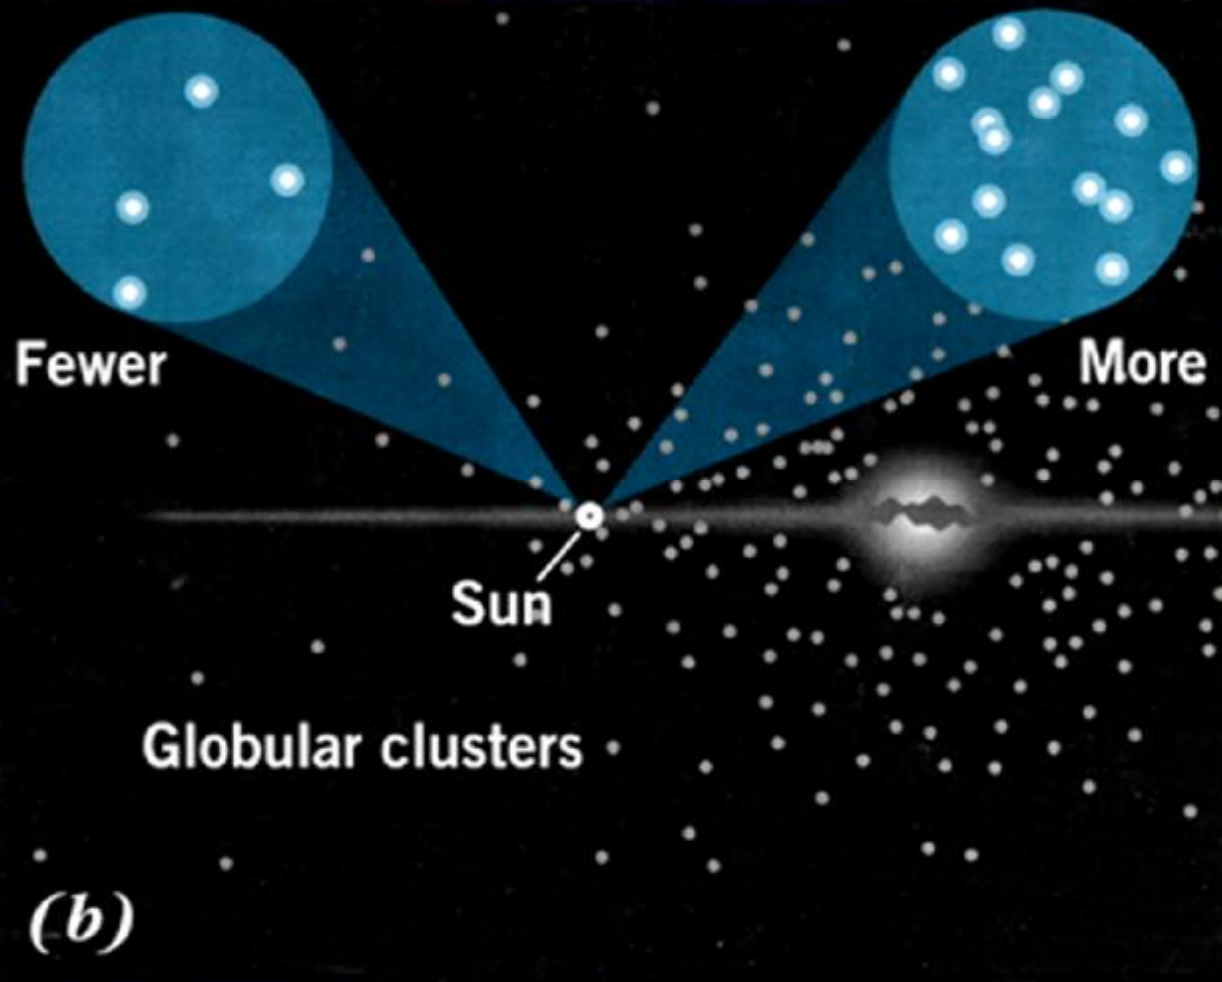

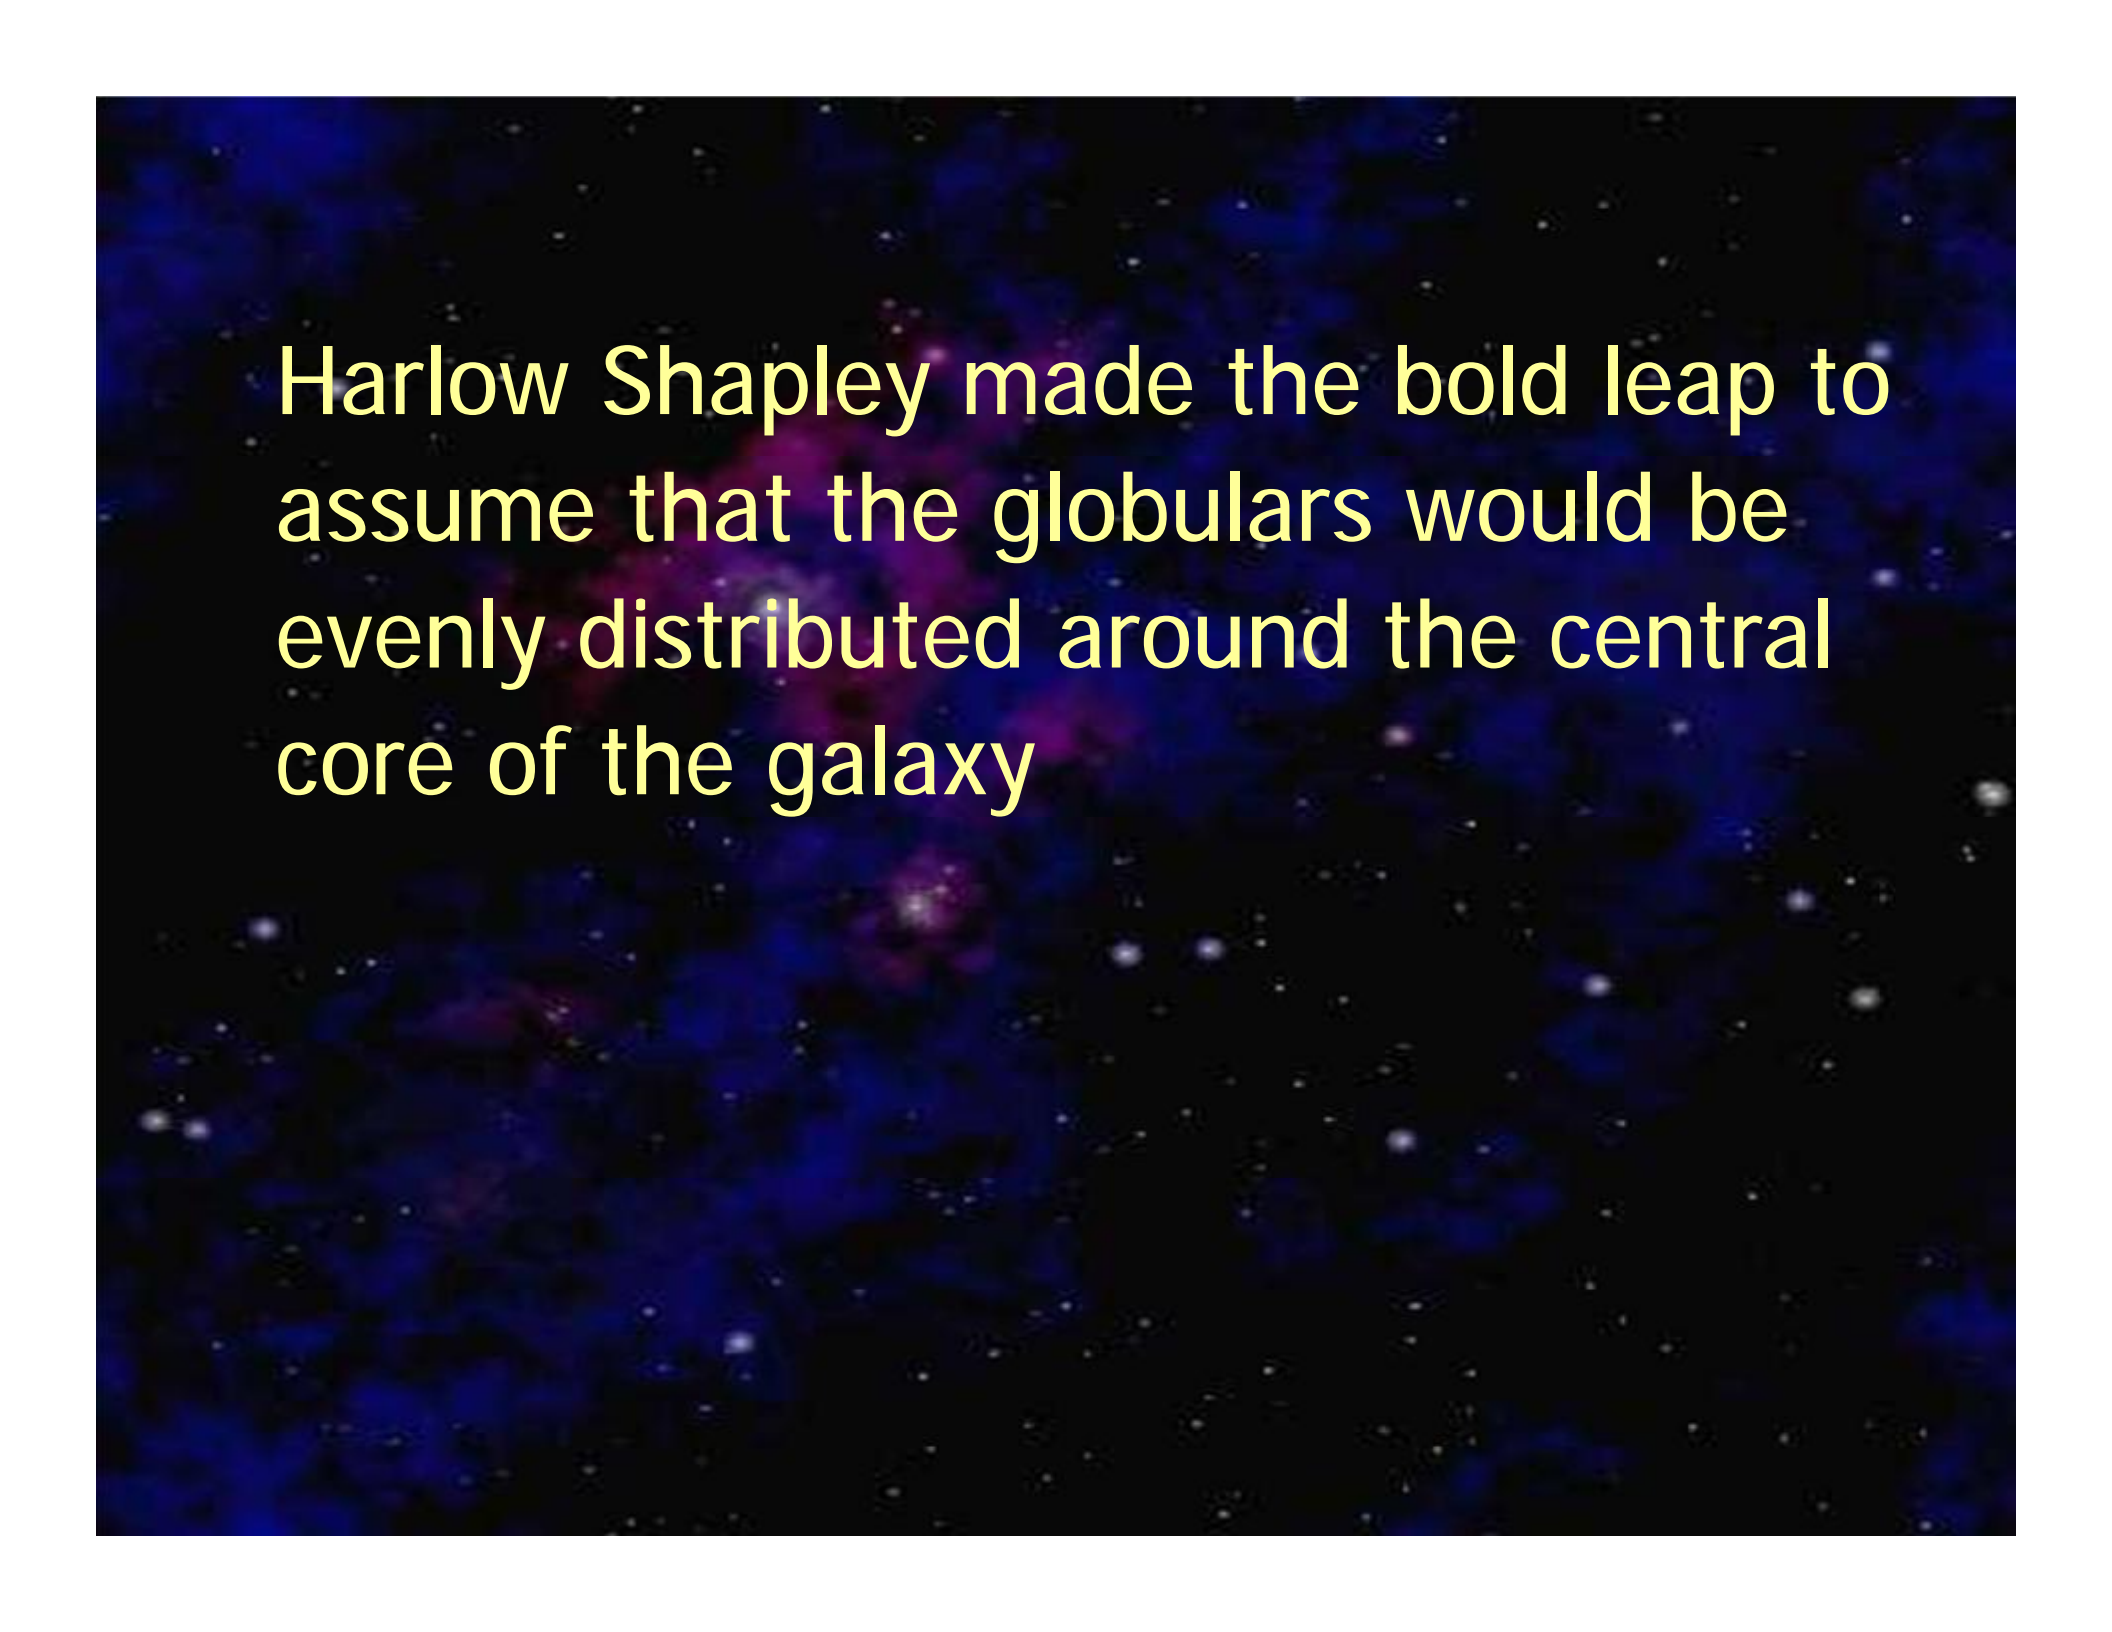

Where is the Sun located in the Milky Way?

- n Harlow Shapley (1915)
- n Globular Clusters

Harlow Shapley made the bold leap to assume that the globulars would be evenly distributed around the central core of the galaxy

Where are Globular Clusters found

Where are Globular Clusters found

GALAXIES

What is the shape of the Milky Way Galaxy?

William Herschel

Near-infrared all-sky (cool stars)

Atomic Hydrogen (all sky)

Interacting Galaxies

Cartwheel Galaxy

Particularly in rich clusters, galaxies can collide and interact.

Galaxy collisions can produce ring galaxies and

NGC 4038/4039

tidal tails.

Often triggering active star formation:
Starburst galaxies

What we see is NOT what we may get!!

Great enigmas still exist

Reference line

Observed vs. Predicted Keplerian

The only explanation for this curve is that a large Fraction of the matter in a galaxy exists as a vast halo around the core of the galaxy

First observed and predicted by Fritz Zwicky...1930's

Since the matter is not visible, called dark matter!

~90% of all the matter in a galaxy is dark matter

What are the scales we have learned about?

1. The Earth-Moon ~200,000 miles
2. The Solar System ~1,000,000,000 miles
3. The local stellar neighbor ~1,000,000,000,000,000 miles
4. The galaxy, globular clusters ~1,000,000,000,000,000,000 miles
5. The local galactic neighbor ~100,000,000,000,000,000,000 miles
6. Our neighborly galaxy cluster ~10,000,000,000,000,000,000,000 miles
7. SuperClusters ~100,000,000,000,000,000,000,000 miles
8. The very edge....? ~100,000,000,000,000,000,000,000,000.... miles

What are the scales we have learned about?
How are their distances determined?

- | | |
|----------------------------------|--|
| 1. The Earth-Moon | Direct, parallax, radar, light |
| 2. The Solar System | Direct, parallax, radar |
| 3. The local stellar neighbor | Direct, parallax |
| 4. The galaxy, globular clusters | Indirect, calibrated Period-Luminosity |
| 5. The local galactic neighbor | Indirect, calibrated Period-Luminosity |
| 6. Our neighborly galaxy cluster | Indirect, calibrated Period-Luminosity |
| 7. SuperClusters | Hubble Expansion, |
| 8. The very edge....? | ~100,000,000,000,000,000,000,000,000.... miles |

Distances to the galaxies

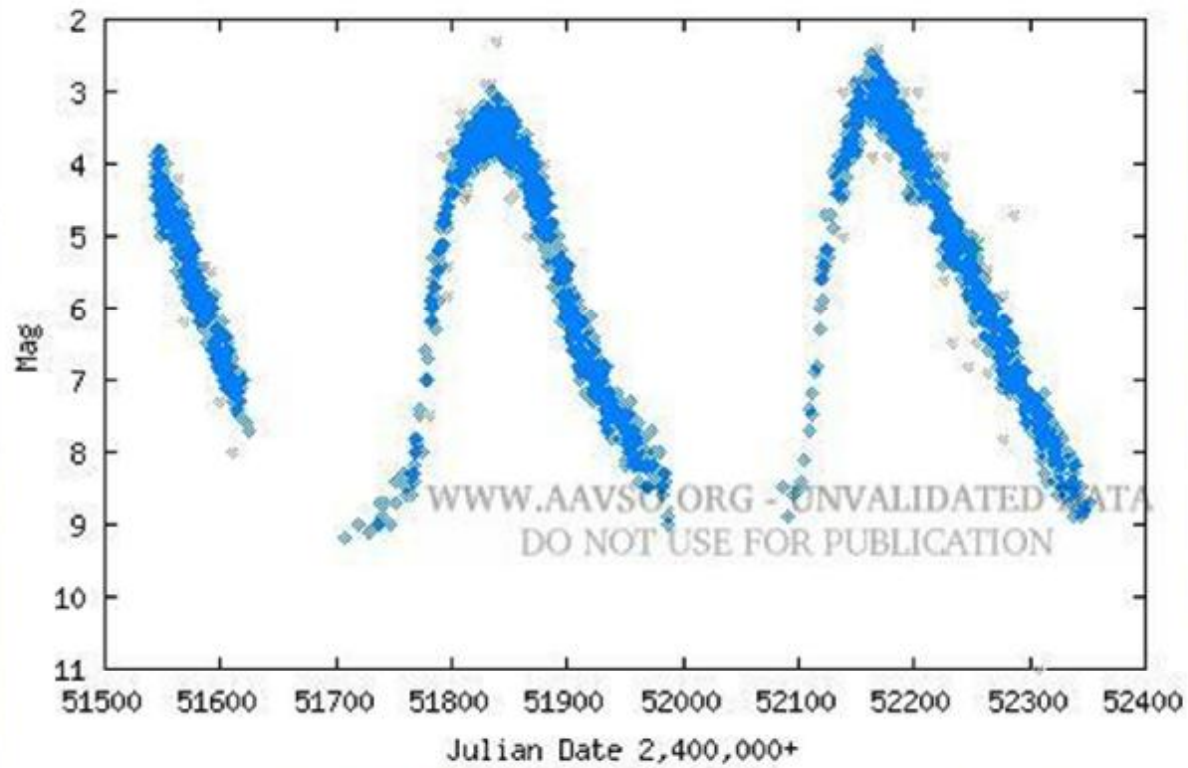

- Much too distant to use direct method (trig. Parallax)
- Some of the brighter stars on the MS can be used for spectroscopic parallax. Tough to get spectrum to type
- Period-Luminosity relationship Cepheid variables
Extremely luminous (very large R)

RR Lyr and Cepheid Variables: a class of pulsating stars

Period-Luminosity Relationship

Edwin Hubble accomplished 2 great things:

1. 1924 he was able to recognize Cepheids (variable stars) in nearby galaxies and once and for all showed that these were separate "island universes".

Cepheid Variable in M100
HST-WFPC2

The History of Astronomy is a history of the displacement of man from being the Center of everything

Pre 1500's

Earth and man center of all there is (Universe)

After Copernicus (~1500)

OK, sun is at the center, but man is center of everything, center of galaxy, center of Universe

1910-1920

Oh no! we are not at center of galaxy but out toward the edge but at least our galaxy is at the center of everything!!

-study of globular clusters, their distribution and variables contained in them

1925-1930

The Universe is full of galaxies, rushing away from each other we have no special place whatsoever!!

-study of variable stars (pulsating) in distant galaxies

Edwin Hubble accomplished 2 great things:

1. 1924 he was able to recognize Cepheids (variable stars) in nearby galaxies and once and for all showed that these were separate "island universes".
2. 1929 he showed through the analysis of red shifts of galaxies (spectroscopy) that the more distant a galaxy is the faster it is rushing away from us.

"Expanding Universe"

Doppler Shift of Light: measuring the speed of objects

$$z = v/c = (l - l_0) / l_0$$

v = velocity of object

c = velocity of light (300,000 km/sec)

l₀ = rest wavelength

l = measured wavelength

$V = H_0 D$ or $H_0 = V/D$

H_0 is the Hubble Constant

$H_0 = \sim 70 \text{ km/sec/Mpc}$

$$H_0 = \sim 70 \text{ km/sec/Mpc}$$

1 Mpc = 1 million parsecs = 3.26 million light years

Edwin Hubble accomplished 2 great things:

1. 1924 he was able to recognize Cepheids (variable stars) in nearby galaxies and once and for all showed that these were separate “island universes”.
2. 1929 he showed through the analysis of red shifts of galaxies (spectroscopy) that the more distant a galaxy is the faster it is rushing away from us.

“Expanding Universe”

Sidebar: In 1916 Albert Einstein published his opus on General relativity. This theory predicted that the universe should be expanding!!! Since the prevailing thinking of the time was that the universe was static (not expanding or contracting), he added a term to his relativity equations that made the universe static.

Einstein 14 years later called it was his greatest scientific blunder.

Georges Lemaitre
